

Model-View-ViewModel (MVVM) Architecture

Dr. Abdelkarim Erradi
CSE@QU

Outline

1. Model-View-ViewModel (MVVM)
2. ViewModel
3. State variables
4. Flow

MVVM Architecture

Model-View-ViewModel (MVVM) Architecture

View = UI to display state & collect user input

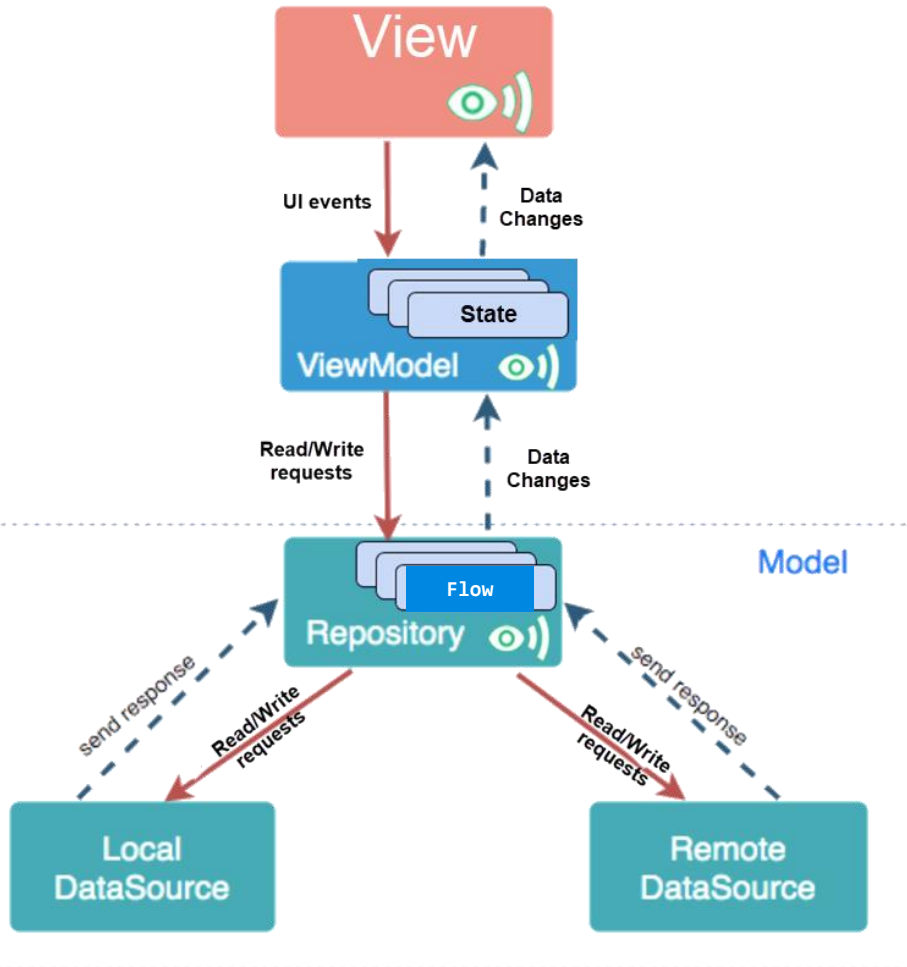

- It **observes** state changes from the ViewModel to update the UI accordingly
- Calls the ViewModel to handle events such as button clicks, form input, etc.

ViewModel

- Manages **state** (i.e, data needed by the UI)
 - Interacts with the Model to read/write data based on user input
 - Expose the state as **Observables** that the UI can subscribe-to to get data changes
- Implements UI logic / computation (e.g., data validation)

Model - handles data operations

- Model has **entities** that represent app data
- **Repositories** read/write data from either a Local Database (using [Room](#) library) or a Remote Web API (using [Ktor](#) library)
- Implements data-related logic / computation

MVVM Key Principles

- Separation of concerns:
 - View, ViewModel, and Model are **separate components** with distinct roles
- Loose coupling:
 - ViewModel **has no direct reference to the View**
 - View never accesses the model directly
 - Model unaware of the view
- Observer pattern:
 - View observes the ViewModel (to get data changes)
 - ViewModel observes the Model (to get data changes)
- Inversion of Control:
 - Uses Dependency Injection instead of direct instantiation of objects
e.g., `val scoreViewModel = viewModel<ScoreViewModel>()`

Advantages of MVVM

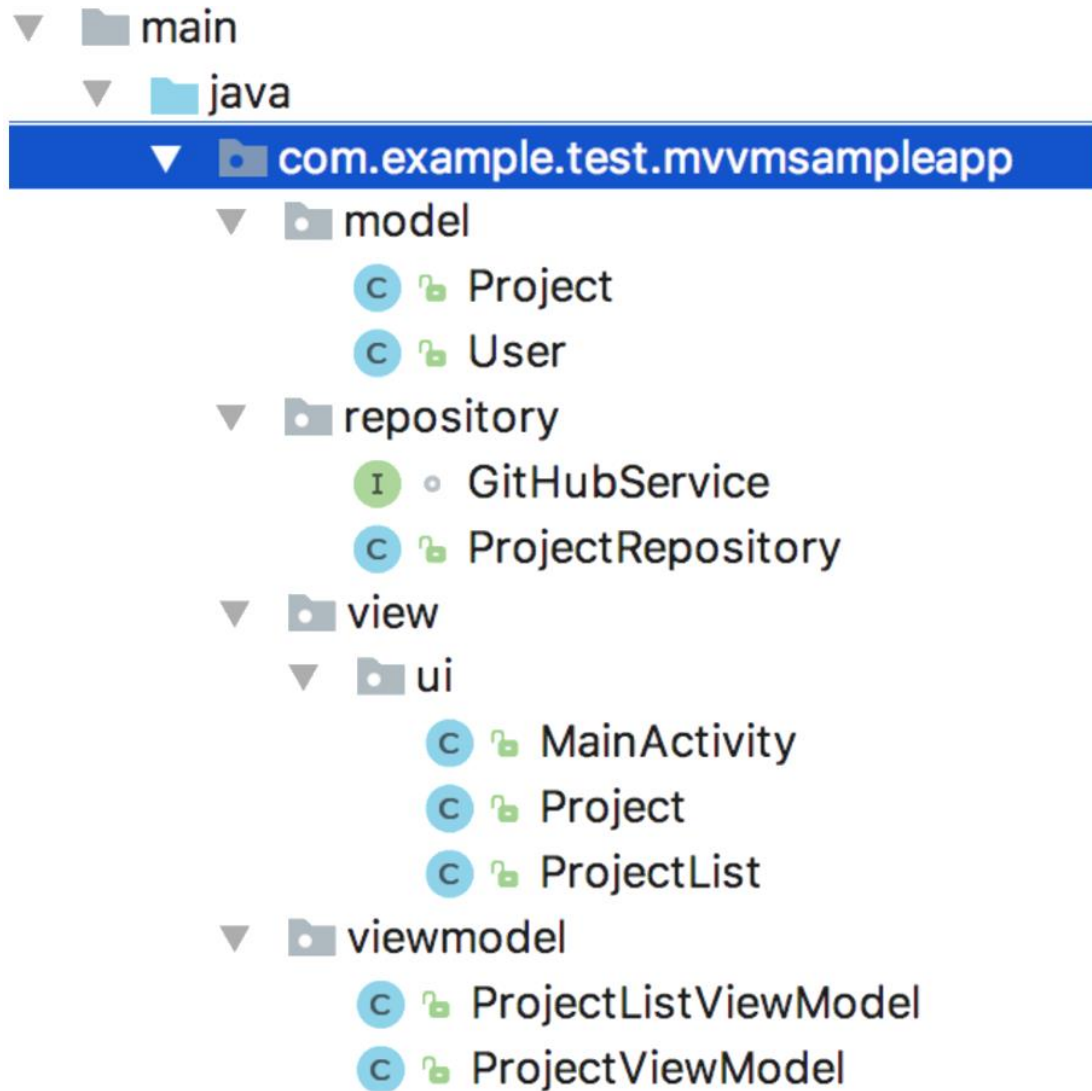

- ***Separation of concerns*** = separate UI from app logic
 - App logic is not intermixed with the UI. Consequently, code is cleaner, flexible and easier to understand and change
 - Allow changing a component without significantly disturbing the others (e.g., View can be completely changed without touching the model)
 - Easier **testing** of the App components

MVVM => Easily **maintainable** and **testable** app

Android Architecture Components

- Android architecture components are a collection of libraries to ease developing MVVM-based Apps
- Part of [Android Jetpack](#)  They include:
 - [ViewModel](#) stores UI-related data that isn't destroyed on screen rotation
 - [StateFlow](#) data holder that notifies the View when the model data changes
 - [Room](#) to read / write data to local SQLite database

Recommended Project Structure

You may
organize the
view by feature

ViewModel

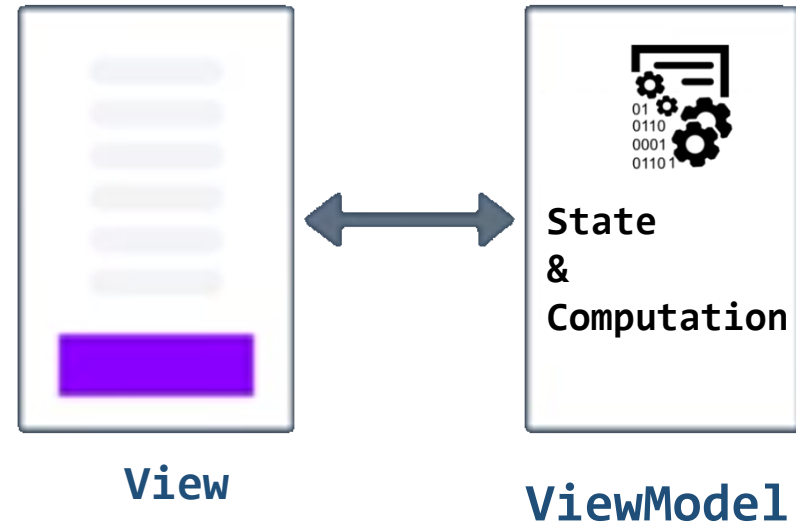

Lifecycle Aware

Survives Config Changes

ViewModel

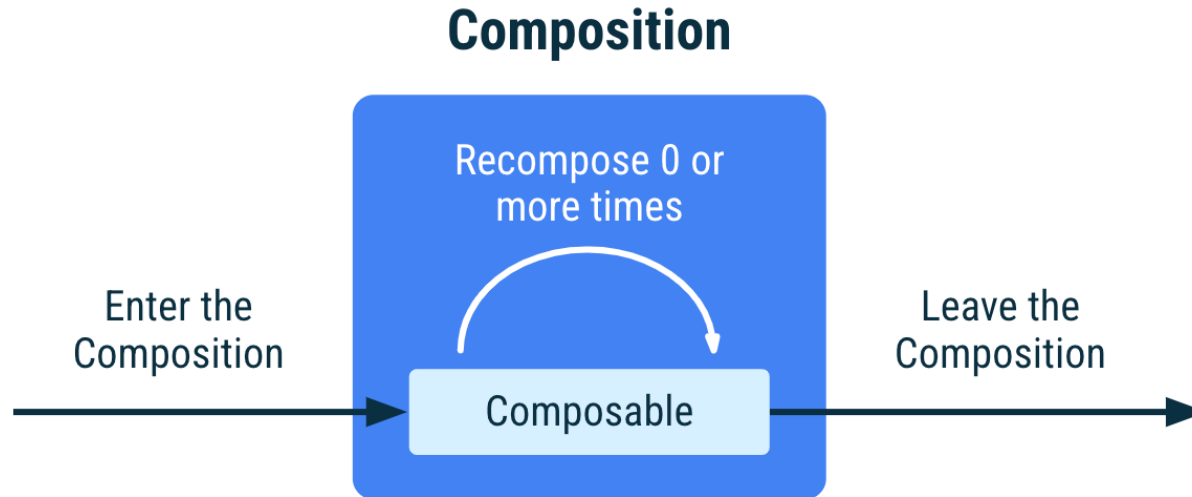

- ViewModel is used to **store and manage state** (i.e., data needed by the UI)
 - in a lifecycle conscious way
 - allows **state** to survive device configuration changes such as *screen rotations* or *changing the device's language*
- If the system destroys or re-creates a UI component (e.g., when the screen rotates), any state stored in the View is lost
 - State is NOT retained across configuration changes (landscape/portrait)

Use **ViewModel**:

- Manages state
- Read/write data from a Repository

Composable Lifecycle

- When the screen is displayed for the first time, the Composable **enters** the Composition, gets **recomposed** 0 or more times, and **leaves** the Composition
- Recomposition is triggered by a change to a `State<T>` object. Compose tracks these and runs all composables in the Composition that read that particular `State<T>`

<https://developer.android.com/jetpack/compose/lifecycle>

Activity Lifecycle

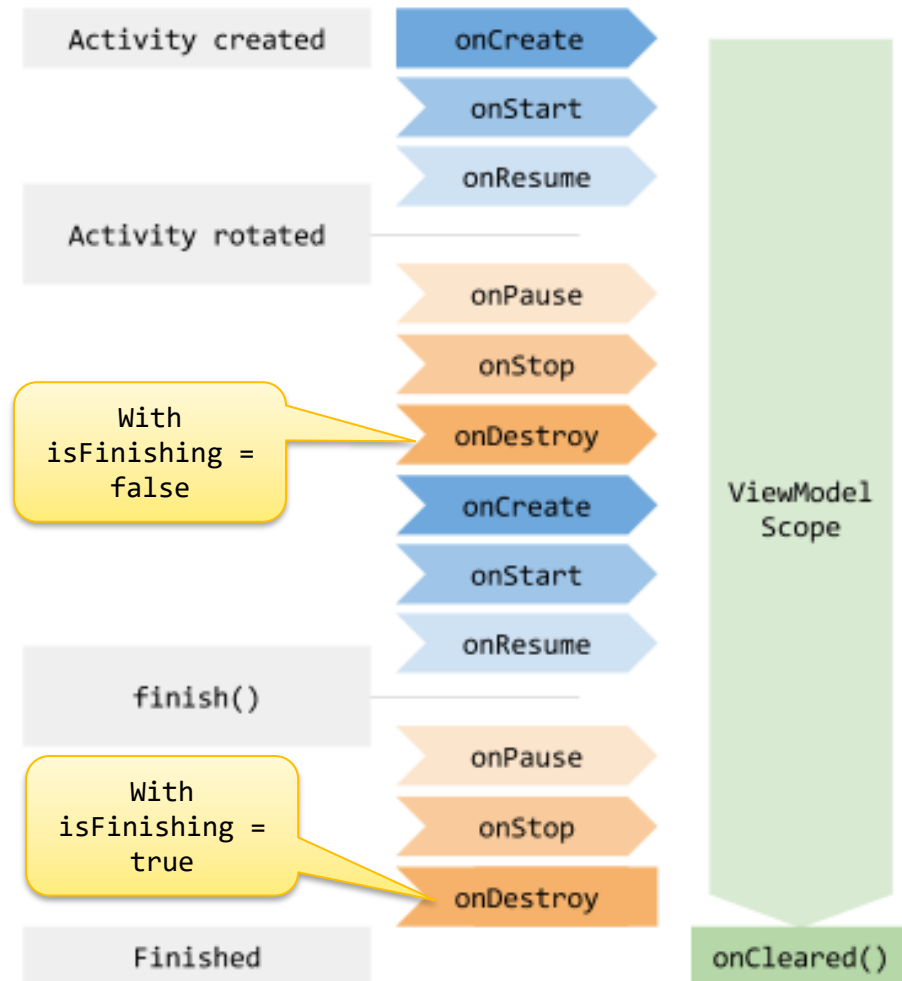

An activity has essentially **four states**:

- **Resumed** if the activity is in the foreground of the screen (has focus)
- **Started** if the activity has lost focus but is still visible (e.g., beneath a dialog box).
 - When the user returns to the activity, it is **resumed**
- **Created** if the activity is completely obscured by another activity.
 - When the user navigates to the activity, it must be **restarted** and restored to its previous state.
- **Destroyed** when the user closes the app or if the activity is killed (when memory is needed or due to `finish()` being called on the activity)

ViewModel Lifecycle

- ViewModel object can be scoped to the main activity
- However, it has a **longer lifespan** compared to the associated Activity which may undergo a rotation and get recreated
- It remains in memory until the activity is completely destroyed
 - When the activity is recreated (after a screen rotation) the associated ViewModel remains alive

ViewModel Example

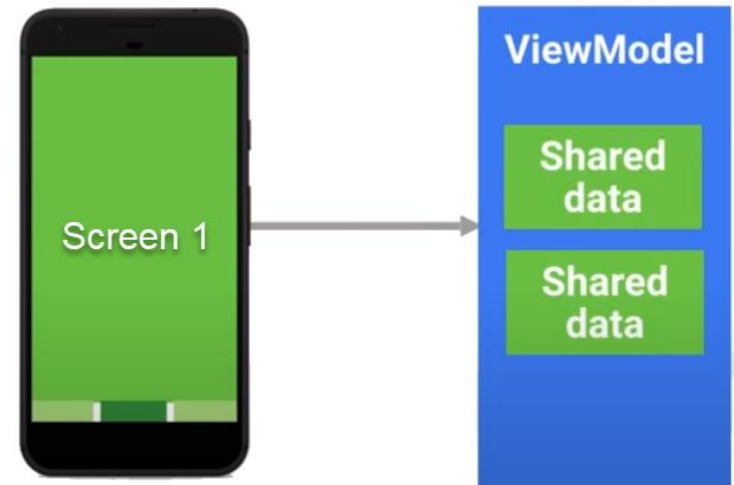

```
class ScoreViewModel : ViewModel() {  
    // Private mutable state variables  
    private var _team1Score = mutableStateOf(0)  
    // Public State variables  
    val team1Score : State<Int> = _team1Score  
    fun onIncrementTeam1Score() { _team1Score.value++ }  
}
```

```
@Composable  
fun ScoreScreen() {  
    // Get an instance of the ScoreViewModel  
    val scoreViewModel = viewModel<ScoreViewModel>()  
    Text(text = scoreViewModel.team1Score.value)  
    Button(onClick = { scoreViewModel.onIncrementTeam1Score() }) {  
        Text(text = "+1")  
    }  
    ...  
}
```

Shared data between Screens using ViewModel

- Screens can **share** data using a shared **View Model** class that extends `ViewModel()`

`@Composable`

```
fun ProfileScreen(userId: Int) {  
    /* Get an instance of the shared viewModel  
       Make the activity the store owner of the viewModel  
       to ensure that the same viewModel instance is used for all screens */  
    val userViewModel = viewModel<UserViewModel>()  
    val user = userViewModel.getUser(userId)  
    ... }  

```

“no contexts in ViewModels” rule

- ViewModel should **not be aware of the View** who is interacting with
=> It should be **decoupled** from the View

- ViewModel should not hold a reference to Activities or Views (i.e. Composables)
- Should not have any Android framework related code
- As this defeats the purpose of separating the UI from the data
- Can lead to **memory leaks** and **crashes** (due to null pointer exceptions) as the ViewModel outlives the View
 - if you rotate an Activity 3 times, 3 three different Activity instances will be created, but you only have one ViewModel instance

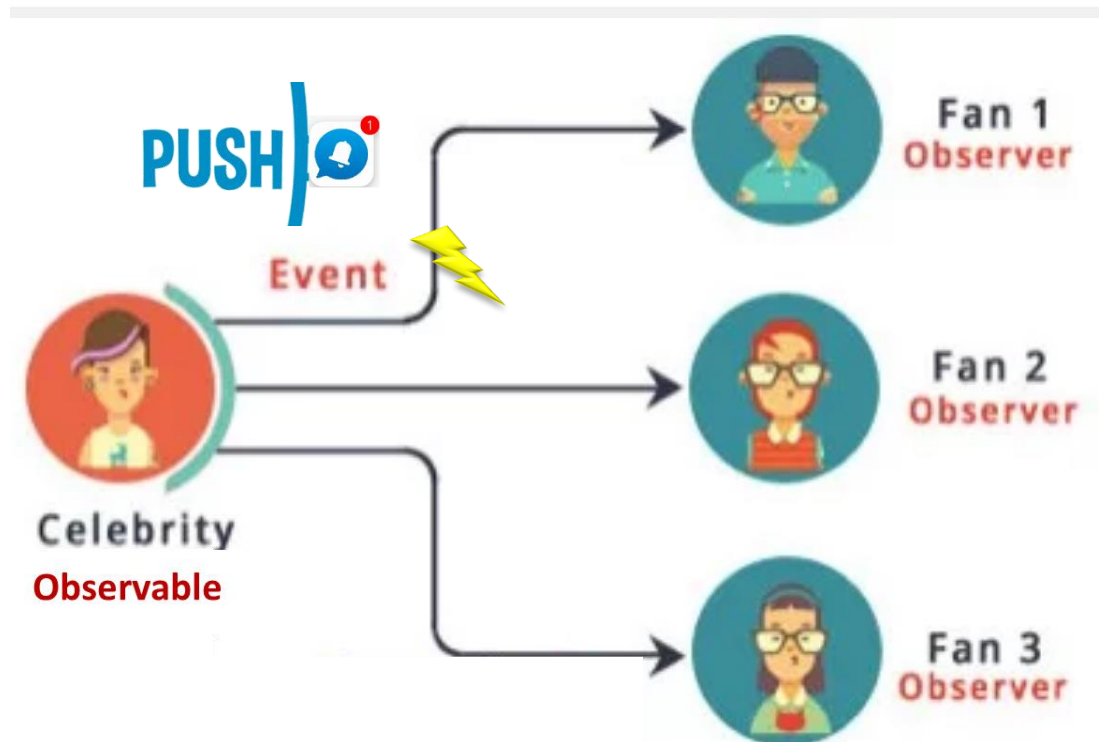

State variables

State variables

- State in an app is any value that can change over time
- A State variable is an **observable data holder** whose reads and writes are observed by Compose to trigger UI recomposition
 - State variable warps around an object and allows the view to **observe** it
- The ViewModel exposes **State** variables that the View observes and update the UI accordingly
 - This decouples the ViewModel from the View: the **ViewModel does NOT have any direct reference to the View**
 - The View can observe the ViewModel State variables for changes then update the UI (aka recomposition)

Observable - Real-Life Example

- A celebrity who has many fans on Instagram. Fans want to get all the latest updates (photos, videos, posts etc.). Here fans are **Observers** and celebrity is an **Observable**

Example - State variable

```
class ScoreViewModel : ViewModel() {  
    // Private mutable state variables  
    private var _team1Score = mutableStateOf(0)  
    // Public State variables  
    val team1Score : State<Int> = _team1Score  
    fun onIncrementTeam1Score() { _team1Score.value++ }  
}
```

```
@Composable  
fun ScoreScreen() {  
    // Get an instance of the ScoreViewModel  
    val scoreViewModel = viewModel<ScoreViewModel>()  
    Text(text = scoreViewModel.team1Score.value)  
    Button(onClick = { scoreViewModel.onIncrementTeam1Score() }) {  
        Text(text = "+1")  
    }  
    ...  
}
```

Other Observable Types

- [mutableStateListOf\(\)](#) creates an instance of MutableList that is observable
- [mutableStateMapOf\(\)](#) creates an instance of MutableMap<K, V> that is observable
- [Flow](#): a flow is a type that can emit a stream of values overtime
 - e.g., you can use a flow to receive live updates from a database
- [StateFlow](#) is lifecycle-aware observable data holder class that notifies the View when the model data changes
 - Meaning that StateFlow only sends updates to app component observers that are in an active lifecycle state

Flow

What is Flow?

 Stream of values produced one by one over time instead of all at once

-  as opposed to functions that return only a single value

-  Values could be generated from network requests or database calls

 Operators like map, filter can be used to transform

```
fun stream(): Flow<String> = flow {  
    emit("🐼") // Emits the value upstream   
    emit("⚽")  
    emit("🦄")  
}
```

Flow motivation

- Asynchronous stream of data: returns multiple asynchronously computed values
- Makes the app responsive and boost its performance as data is received from the server asynchronously in the background using as Flow to avoid blocking specially when the data fetching is long running
- Once the data is received and collected, then it is used to update the UI

```
object WeatherRepository {
    private val weatherConditions = listOf("Sunny", "Windy", "Rainy", "Snowy")
    fun getWeather(): Flow<String> =
        flow {
            var counter = 0
            while (true) {
                counter++
                delay(3000)
                emit(weatherConditions[counter % weatherConditions.size])
            }
        }
}
```

```
class WeatherViewModel : ViewModel() {
    val weatherFlow: Flow<String> = WeatherRepository.getWeather()
}
```

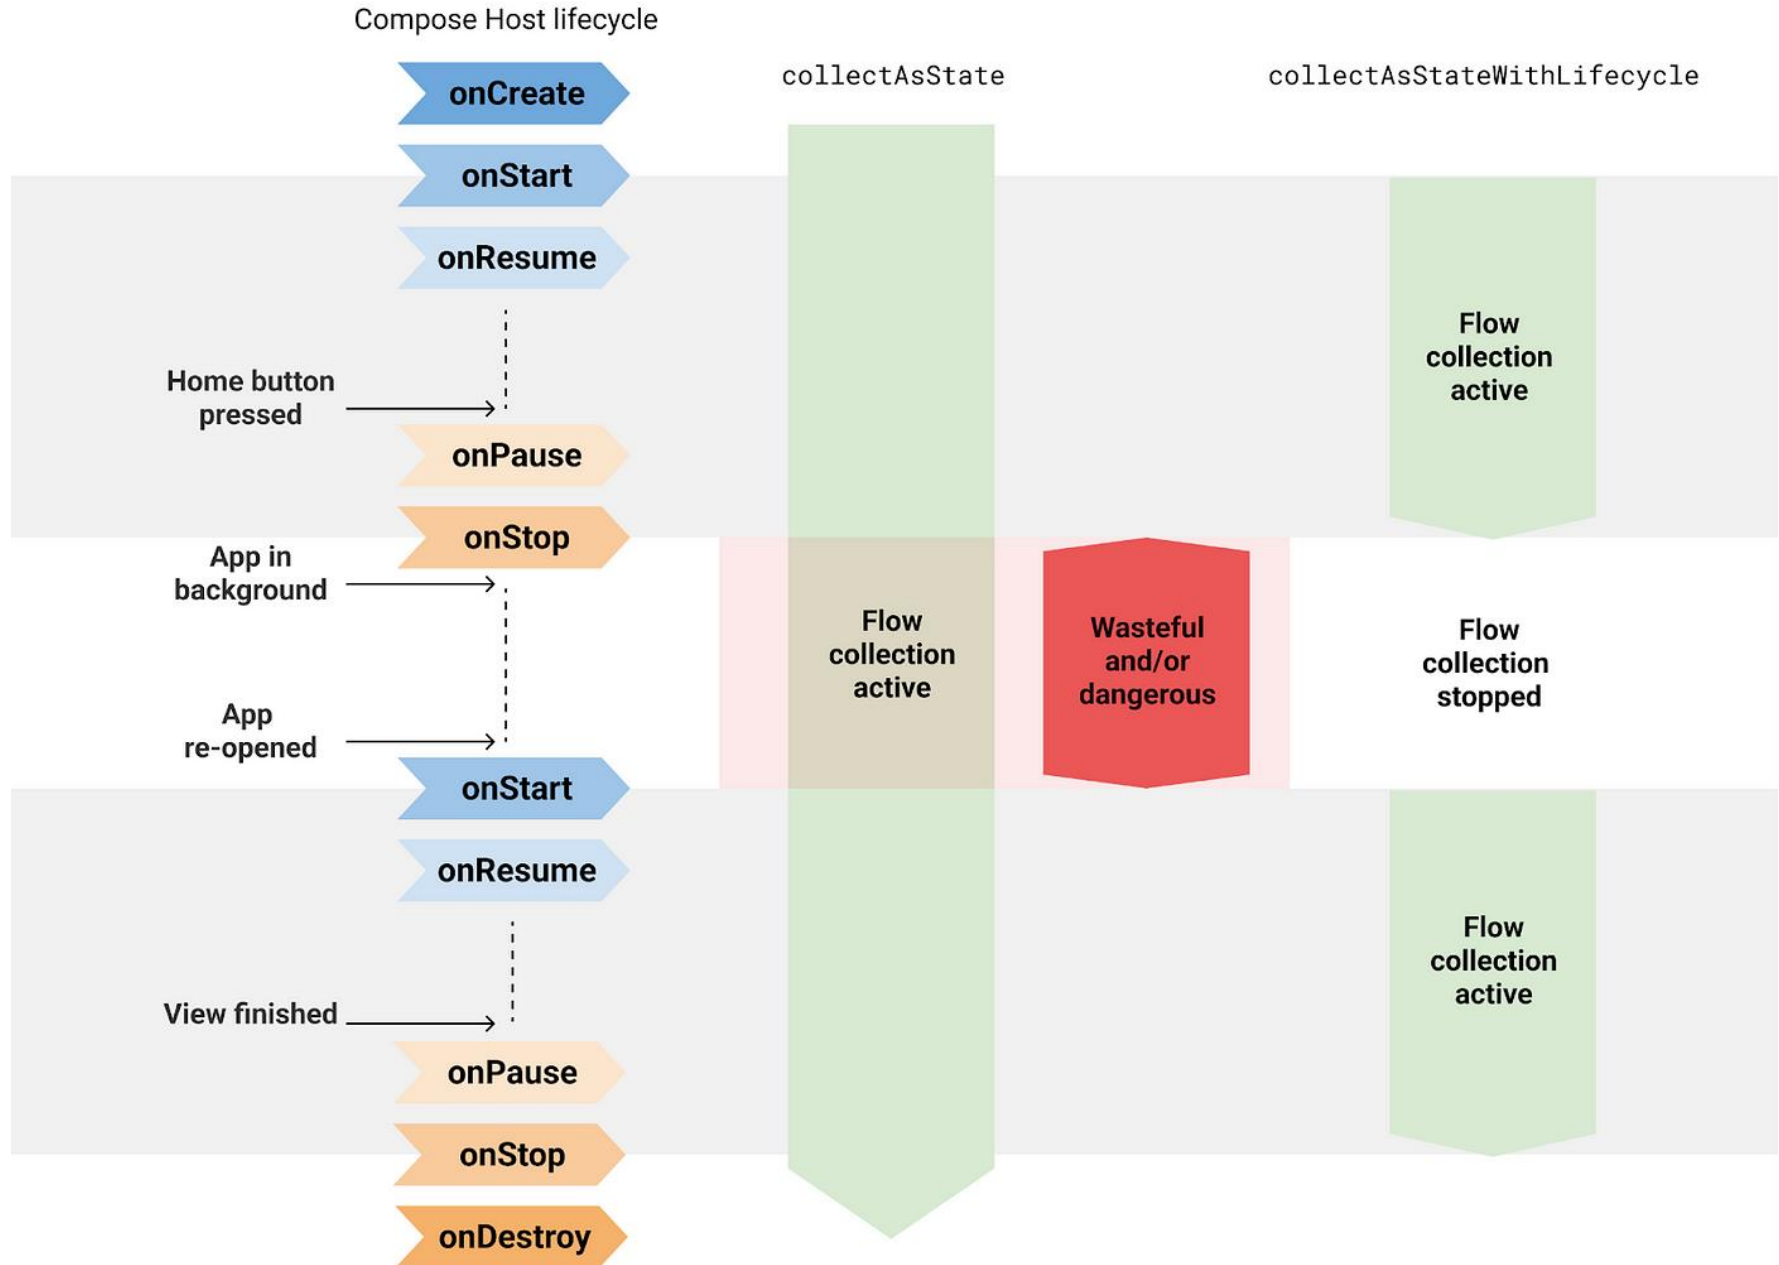

```
@Composable
fun ScoreScreen() {
    val weatherViewModel = viewModel<WeatherViewModel>()
    val weatherFlow = weatherViewModel.weatherFlow.
        collectAsStateWithLifecycle (initialValue = "")
    // Recomposes whenever weatherFlow changes
    Text(
        text = "Weather: ${weatherFlow.value}" )
    ... }
```

collectAsStateWithLifecycle

- `collectAsStateWithLifecycle()` collects values from a Flow and transforms its latest value into a Compose State. Causing recomposition when a new value is received from the Flow
 - Every time a new flow emission occurs, the returned State will be updated causing recomposition
- It does so in a lifecycle-aware manner, allowing the app to save unneeded app resources when the app is in the background
 - `collectAsStateWithLifecycle` start collecting values from the flow only when the UI is visible and stop collecting values from the flow when the UI is not visible on the screen
- Requires adding this dependency to build.gradle

```
implementation("androidx.lifecycle:lifecycle-runtime-compose:2.6.2")
```

In the View, collect Flow using **collectAsStateWithLifecycle**

StateFlow

- Flows are **cold** by default. This means that if we subscribe to a Flow, the code in its builder will get executed each time we subscribe to it.
 - This is something that you might not want to do when the app goes through a configuration change. To solve this, StateFlow can be used.
- **StateFlow** is a **hot** observable that stores the latest value. When created, it requires you to pass an initial state to it and any observer can check its current value or subscribe to it to receive updates with the current value as it changes
 - You can also convert any flow to a **StateFlow** using the **stateIn** operator

.stateIn

- The ViewModel can convert a Flow returned by the model into StateFlow using **stateIn**

```
val timeRemainingFlow: StateFlow<String> =  
    DataRepository.countDownTimer(5)  
        .stateIn(  
            scope = viewModelScope,  
            // Sharing is started when the first subscriber appears and never stops.  
            started = SharingStarted.Lazily,  
            initialValue = ""  
        )
```

`started = SharingStarted.Lazily` keep collecting the flow data even if the app is NOT visible

.stateIn

- The `started` parameter is used to specify the strategy that controls when sharing is started and stopped
- ***WhileSubscribed*** allows you to configure a delay in milliseconds between the time the last subscriber disappears and the time we stop the upstream flows.
 - E.g., You can use ***WhileSubscribed(5000)*** to keep the upstream flow active for 5 seconds more after the disappearance of the last collector. That avoids restarting the upstream flow after a configuration change.
 - After 5 seconds if the app remains in the background, Flow collection is stopped to save battery and other resources

```
val newsFlow: StateFlow<String> = DataRepository.getNews().stateIn(  
    scope = viewModelScope,  
    started = WhileSubscribed(5000),  
    initialValue = ""  
)
```

Flow Operators

- Flow has operators similar to collections such as map, filter and reduce

```
(1..5).asFlow()  
    .filter { it % 2 == 0 }  
    .map { it * it }  
    .collect { println(it.toString()) }
```

```
val result =(1..5).asFlow()  
                .reduce { a, b -> a + b }  
println("result: $result")
```
