Data Layer

Dr. Abdelkarim Erradi
CSE@QU

Outline

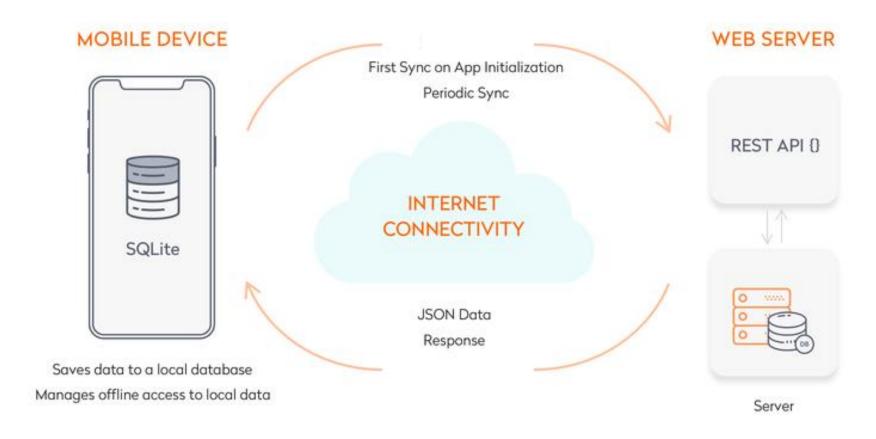

- Data persistence options on Android
- 2. Room programming model
- 3. <u>Type Converters, Embedded object, Foreign keys & Map Queries</u>
- 4. Observable Queries using LiveData

Data persistence options on Android

Offline app with Sync

 Cache relevant pieces of data on the device. App continues to work offline when a network connection is not available.

 When the network connection is back, the app's repository syncs the data with the server.

MVVM Data Layer

- The Data Layer manages the app data:
 - implements read/write operations
 - notifies the ViewModel of data changes
- It includes data models, data sources and repositories:
 - Data models define the entities that holds the app data (i.e., in-memory representations of the data)
 - A data source is responsible for reading and writing data to a single source such as a database or a network service.
 - The repository exposes, updates, and synchronizes data using a local datasource and/or a remote datasource + implements datarelated logic

Data Storage Options on Android

Preferences DataStore

- Lightweight mechanism to store and retrieve key-value pairs
- Typically used to store application settings (e.g., app theme, language), store user details after login

Files

 Store unstructured data such as text, photos or videos, on the device or removable storage

• SQLite database

Store structured data (e.g., posts, events) in tables

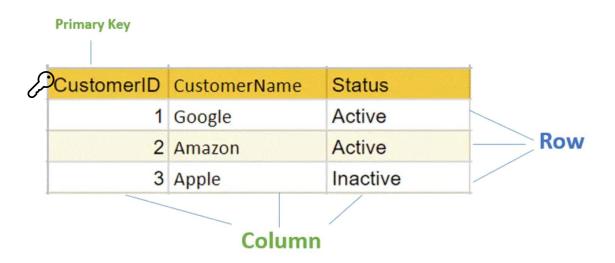

Cloud Data Stores

o e.g.,

Relational Database

- Database allows persisting structured data
- A relational database organizes data into tables
 - A table has rows and columns
 - Tables can have relationships between them
- Tables could be queries and altered using SQL

SQL Statements

- Structured Query Language (SQL)
 - Language used to define, query and alter database tables
 - SQL is a language for interacting with a relational database
- Creating data:

```
INSERT into Person (firstName, lastName)
VALUES ("Ahmed", "Sayed")
```

Reading data:

```
SELECT * FROM Person WHERE lastName = "Sayed"
```

Updating data:

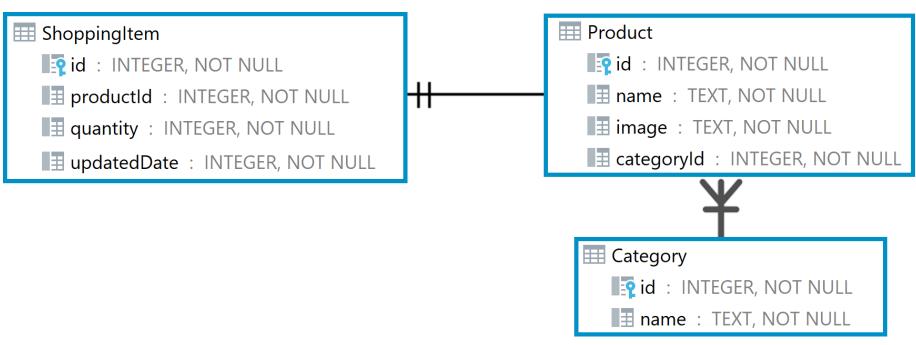

```
UPDATE Person SET firstName = "Ali" where
   lastName = "Sayed"
```

Deleting data:

DELETE from Person where lastName = "Sayed"

Database Schema of Shopping List App

- The Entity Relationship (<u>ER</u>) diagram of the Shopping List App database
 - A ShoppingItem has an associated Product
 - Product has a Category
 - Category has many products

Querying Multiple Tables with Joins

- Combine rows from multiple tables by matching common columns
 - For example, return rows that combine data from the Product and Category tables by matching the Product.categoryId foreign key to the Category.id primary key

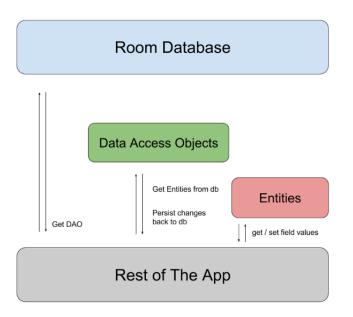

select p.id, p.name, p.image, c.name category

from Product p **join Category c on** p.categoryId = c.id

where p.categoryId = '1'

id	name	image	category
1	Grapes	Ý	Fruits
2	Melon	•	Fruits
3	Watermelon	w	Fruits
4	Banana	2	Fruits
5	Pineapple	š	Fruits
6	Mango		Fruits (
7	Red Apple	Ŭ	Fruits
8	Green Apple	$\overset{\sim}{\Box}$	Fruits
9	Pear	•	Fruits
10	Peach	Ď	Fruits

Room programming model

Room Library

- The **Room** persistence library provides an abstraction layer over SQLite to ease data management
 - Define the database, its tables and data operations using annotations
 - Room automatically translates these annotations into SQLite instructions/queries to be executed by the DB engine

plugins { ...

Dependencies:

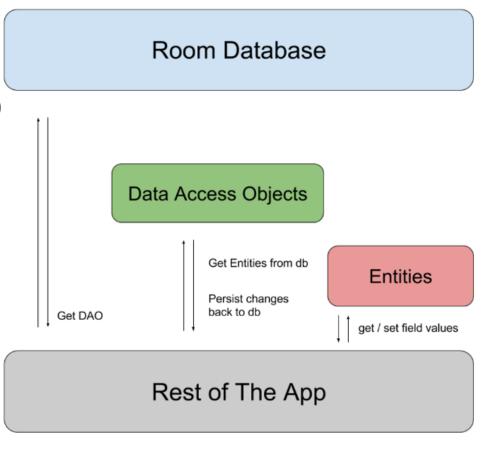

```
id ("com.google.devtools.ksp")
                                                     version "1.9.10-1.0.13"
val roomVersion = "2.6.0"
implementation("androidx.room:room-runtime:$roomVersion")
annotationProcessor("androidx.room:room-compiler:$roomVersion")
// Kotlin Symbol Processing (KSP) - for processing annotations
ksp("androidx.room:room-compiler:$roomVersion")
// Kotlin Extensions and Coroutines support for Room
implementation("androidx.room:room-ktx:$roomVersion")
```

Room architecture diagram

Working with Room

- Model DB Tables as regular Entity Classes
- Create Data Access Objects (DAOs)
 - DAO interface methods are annotated with queries for Select, Insert, Update and Delete
 - DOA implementation is autogenerated by the complier
 - DOA is used to interact with the database
- 3. RoomDatabase → holds a connection to the SQLite DB and all the operations are executed through it

3 major components in Room

Room main components

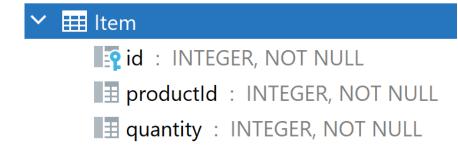

- Entity

 each entity class is mapped to a DB table
 - Kotlin class annotated with @Entity to map it to a DB table
 - Must specify one of the entity properties as a primary key
 - Table name = Entity name & Column names = Property names (but can be changed by annotations)
- Data Access Object (DAO) → has methods to read/write entities
 - Contains CRUD methods defining operations to be done on data
 - Interface or abstract class marked as @Dao
 - One or many DAOs per database
- Database → where data is persisted
 - abstract class that extends RoomDatabase and annotated with @Database

Entity

- Entity represents a database table, and each entity instance corresponds to a row in that table
 - Class properties are mapped to table columns
 - Each entity object has a Primary Key that uniquely identifies the entity object in memory and in the DB
 - The primary key values can be assigned by the database by specifying autoGenerate = true

```
@Entity
data class Item(
    @PrimaryKey(autoGenerate = true)
    val id: Long = 0
    val productId: Long,
    var quantity: Int)
```

Customizing Entity Annotations

- By default, the name of the entity class is the same as the associated table and the name of table columns are the same as the class properties
 - In most cases, the defaults are sufficient but can be customized
 - Use @Entity (tableName = "...") to set the name of the table
 - The columns can be customized using @ColumnInfo(name = "column_name") annotation
- If an entity has properties that you don't want to persist, you can annotate them using @lgnore

DAO @Query

- @Query used to annotate query methods
- Room ensures compile time verification of SQL queries

```
@Dao
interface UserDao {
    @Query("select * from User limit 1")
    suspend fun getFirstUser(): User
    @Query("select * from User")
    suspend fun getAll(): List<User>
    @Query("select firstName from User")
    suspend fun getFirstNames(): List<String>
    @Query("select * from User where firstName = :fn")
    suspend fun getUsers(fn: String): List<User>
    @Query("delete from User where lastName = :ln")
    suspend fun deleteUsers(ln: String): Int
```

DAO @Insert, @Update, @Delete

- Used to annotate insert, update and delete methods
- Suspend ensure that DB operations are not done on the main UI thread

```
@Dao
interface UserDao {
    @Insert
    suspend fun insert(user: User): Long
    @Insert
    suspend fun insertList(users: List<User>): List<Long>
    @Delete
    suspend fun delete(user: User)
    @Delete
    suspend fun deleteList(users: List<User>)
    @Update
    suspend fun update(user: User)
    @Update
    suspend fun updateList(users: List<User>)
```

Room database class

- Abstract class that extends RoomDatabase and Annotated with @Database
- Provides a singleton dbInstance object created using Room.databaseBuilder()
 to create (if does not exit) and connect to the database
- Serves as the main access point to get DAOs to interact with DB

```
@Database(entities = [Item::class], version = 1)
abstract class ShoppingDB : RoomDatabase() {
    companion object { // Create a singleton dbInstance
        private var dbInstance: ShoppingDB? = null
        fun getInstance(context: Context): ShoppingDB {
            if (dbInstance == null) {
                dbInstance = Room.databaseBuilder(
                    context,
                    ShoppingDB::class.java, "shopping.db"
                ).fallbackToDestructiveMigration().build()
            return dbInstance as ShoppingDB
```

Type Converters, Embedded object, Foreign keys & Map Queries

TypeConverter

- SQLite only support basic data types, no support for data types such as Date, enum, BigDecimal etc. Need to add a TypeConverter for such data types
- Convert an entity property datatype to a type that can be written to the associated table column and vice versa

```
class DateConverter {
    // Convert from Date to a value that can be stored in SQLite Database
    @TypeConverter
    fun toLong(date: Date) : Long = date.time

    // Convert from date Long value read from SQLite DB to a Date value
    // that can be assigned to an entity property
    @TypeConverter
    fun toDate(dateLong: Long) : Date = Date(dateLong)
}

@TypeConverters(DateConverter::class)
abstract class ShoppingDB : RoomDatabase() { ... }
```

Nested @Embedded object

- Nested object annotated with @Embedded -> Room flattens out the embedded object and maps its properties to columns in the DB table
 - User table will have a buildingNo, street and city columns

```
data class Address(val buildingNo: String,
                     val street: String,
                     val city: String)
@Entity

Ⅲ User
data class User (
                                               id: Integer, not null
    @PrimaryKey(autoGenerate = true)
                                               firstName: TEXT, NOT NULL
    var id: Long,
                                               ■ lastName : TEXT, NOT NULL
    val firstName: String,
                                               buildingNo: TEXT, NOT NULL
    val lastName: String,
                                               street: TEXT, NOT NULL
    @Embedded val address: Address
                                               tity: TEXT, NOT NULL
```

Enforce integrity checks with foreign keys

- Foreign key allows integrity checks (e.g., can insert pet only for a valid owner) & cascading deletes
 - onDelete = ForeignKey.CASCADE when owner is deleted then auto-delete associated pets

```
@Entity(foreignKeys = [
        ForeignKey(entity = Owner::class,
                parentColumns = ["id"],
                childColumns = ["ownerId"],
                onDelete = ForeignKey.CASCADE)
        ],
    // Create an index on the ownerId column to speed-up query execution
    indices = [Index(value = ["ownerId"])])
data class Pet(@PrimaryKey val id: Long,
               val name: String, val ownerId: Long)
@Entity
data class Owner(@PrimaryKey val id: Long, val name: String)
```

Queries that Return a Map

For each category return a list of associated products

```
@Query("""
    Select c.*, p.*
    From Category c join Product p on c.id = p.categoryId
    """)
suspend fun getCategoriesAndProducts(): Map<Category, List<Product>>
```

- For each category return the count of associated products
- @MapColumn is required when the key or value column of the map are from a single column

```
@Query("""
    Select c.name categoryName, count(p.id) as productCount
    From Category c join Product p on c.id = p.categoryId
    Group by c.id
    """)
suspend fun getCategoriesAndProductCounts():
Map<@MapColumn(columnName = "categoryName") String,
    @MapColumn(columnName = "productCount") Long>
```

Observable Queries using Flow

Observable Queries

- Observable queries allow automatic notifications when data changes
 - Notifies the app with of any data updates
- We can accomplish this by simply wrapping the return type of our DAO methods with Flow
 - Then collect it from the UI collectAsStateWithLifecycle() or from the ViewModel using stateIn operator
 - o active observers (i.e., UI) get notified when data change

```
// App will be notified of any changes of the Item table data
// Whenever Room detects Item table data change, observeItems will
be called with the new list of items
// No need for suspend function as Flow is already asynchronous
@Query("Select * from Item")
fun observeItems() : Flow<List<Item>>
```

Summary

Major Components

- @Entity Defines table structure
- @Dao An interface with functions to read/write from the database
- @Database Serves as the main access point to get DAOs to interact with DB
